## CONTINUOUSLY CONDUCTIVE UNIPOLAR CANNULA FOR ANESTHESIA

The invention concerns continuously conductive unipolar a cannula for anesthesia.

5

10

F

continuously conductive unipolar cannula for anesthesia produced by the company Pajunk GmbH, D-78187, Geisingen, Germany is known, which has an electrically conductive cannula tube, the tube having an electrically insulated outer covering which extends from the proximal body part out to the distal tip of the cannula tube and leaves exposed the distal tip in its distal end In the area of the proximal body part, the cannula tube is electrically contacted with a connector, which can connected to an electro-stimulation device via a socket or jack. The distal tip of the cannula tube is either provided with a facet cut or is designed as a so-called Sprotte tip as disclosed in DE 30 20 926 C2.

In this known unipolar cannula, the connector for electrothe anesthetic injection hose for stimulation and an provided introduced axially parallel next to each other in the proximal end face of the body part of the cannula tube. unipolar cannula can be placed exactly in the nerve sheath with its distal tip using electro-stimulation, in order to then be able to apply the anesthetic via the feed hose precisely on the nerve.

In the continuously conductive anesthesia, a catheter is placed in the nerve sheath, in order to be able to introduce anesthetic over a longer period of time. In order to introduce a catheter 30

10

using the known unipolar cannula, a plastic introducer cannula is pulled over the cannula tube, which is placed under electrostimulation by means of the unipolar cannula. As soon as the plastic introducer cannula is in place, the unipolar cannula is withdrawn and then the catheter can be introduced through the plastic introduction cannula.

It is further known from DE 36 43 235 C1 and DE 37 12 869 C2, to design a cannula with Sprotte-tip, such that through this cannula itself a catheter can be introduced in place. For this, a ramp or guide is formed in the inside of the distal tip of the cannula tube, which leads to a side outlet opening. A catheter introduced proximally in the cannula tube is led out of the cannula tube via this ramp through the side outlet opening. This cannula is suitable for the placement of a catheter without a supplemental introducer cannula. An electro-stimulation is, however, not possible with this known cannula. Accordingly, this cannula is not provided with an electrical connection for electro-stimulation.

The invention is concerned with the task, of providing a unipolar cannula for the continuous conduction anesthesia, which through simple construction and simple operation unites the placement of the catheter with the advantage of the electrostimulation.

This task is inventively solved by the unipolar cannula with the characteristics of Claim 1.

Advantageous embodiments and further developments of the invention are set forth in the dependent claims.

The inventive unipolar cannula can be placed or located with the help of electrical nerve stimulation. The outer insulating covering of the cannula tube, which leaves only a very small, almost pinpoint area of the tip free, makes possible an extraordinarily precise placement of the tip. The unipolar cannula can itself be used for the guided introduction of the catheter, for which the body part positioned at the proximal end of the cannula tube exhibits an introduction opening, which leads axially aligned into the cannula tube. The connection for electro-stimulation is introduced through the side of the body part and contacts the outside of the electrically conductive cannula tube. The connection thus does not impede or constrict therewith the axial inlet opening of the body part. After the placement of the unipolar cannula with the help of electrostimulation, the catheter can be introduced through the cannula tube, without any requirement that the position of the unipolar cannula must be changed or other measures be taken. Preferably, a releasable or removeable connection is formed with the body introduction opening, preferably a luer-lock the At this connection, an injection hose can be connection. connected if desired, for injection of an initial or a short duration anesthetic. Likewise, a needle can be connected to the releasable connection, for injection of an anesthetic or also for fluids for aspiration for position control. The possibility of using the body part both for the alternative connection of an injection hose or a needle as well as for introduction of the catheter makes the unipolar cannula extremely versatile.

versatility is achieved using an extremely simple and economical design. The manipulation of the unipolar cannula is likewise extremely simple, since the cannula can be employed without changing the position both for the injection or aspiration as well as for the introduction of the catheter. The axially aligned connection of a needle at the proximal body part makes possible also the carrying out of the nerve block with a one-hand technique.

The needle of the cannular tube can be designed with a facet 10 cut, so that the outlet opening is formed by the diagonal cut surface slanted with respect to the cannula axis. In this embodiment, the catheter exits out of the distal needle axially aligned with the cannula tube. This design is suitable, for for the continuous blockage of the interior example, ischiadicus distal ischiadicus, for the positioning of а catheter, or for the seating of a psoas compartment block. Ū

Likewise, the distal tip of the cannula tube can be designed as a Sprotte-tip wherein the catheter, which is introduced through the cannula tube, is guided through the side outlet openings behind the tip by means of a ramp. The catheter thereby exits at an angle of approximately 30° to the cannula axis. This is of advantage in the anesthetic technique, in which a penetration or piercing essentially parallel to the nerve is not possible. This design of the unipolar cannula is employed, for example, in the interscalenary plexus blockage, the vertical-infraclavical plexus blockage, the ischiadicus blockage, and the blockage of the nervus suprascapularis.

This cannula includes an electrically conductive cannula tube 10, which is preferably formed of steel. Depending upon the model, the cannula tube 10 has a length of from 25 to 200mm and a diameter of 0.5 to 1.0mm. In the illustrative embodiment of Figs. 1 and 2, the distal end of the cannula 10 is cut or ground with a facet cut 12 less than 45° to the axis of the cannula tube 10, so that a distal tip 14 is formed. The outer surface electrically of the cannula tube is covered with an 10 The covering extends from the proximal end conductive plastic. of the cannula tube 10 out to the distal tip 14 and leaves free only the distal end area 16 of the tip 14 with a length of maximally approximally 1mm, in which the metal of the cannula tube 10 is exposed.

The proximal end of the cannula tube 10 is positioned co-axially 30 in a body part 18 of plastic and is adhered therewith via a

25

5

hardening adhesive 20. The body part 18 exhibits an essentially cylindrical shape through which a borehole extends co-axially. In the distal area, the inner diameter of this corresponds to the outer diameter of the cannula tube 10 seated in this borehole. The cannula tube 10 projects with its proximal end axially approximately into the middle of the body part 18. In the area of the proximal end of the cannula tube 10, the inner diameter of the body part 18 widens, so that between the inner wall of the body part 18 and the cannula tube 10 a ring gap remains free. In the area of this ring gap, a cylindrical connection socket or jack 22 in electrically conductive contact is pressed against the metallic cannula tube 10. A conductive wire 24 of a stranded conductor 26 is soldered to this metallic connection junction 22. The non-insulated wire 24 runs in the area in which it is soldered with the connection junction 22 axially parallel to the cannula tube 10 in the The insulated stranded conductor 26 then distal direction. bends away at a right angle from this axially parallel direction and extends radially through the body part 18 towards the The opening of the body part 18, through which the outside. connection stranded conductor 26 exits, is filled with a hardening adhesive 28.

The ring gap between the inner wall of the bore of the body part 18 and the proximal end of the cannula tube 10 with the connection socket or jack 22 and the wire 24 is filled with a hardening plastic 30.

The plastic 30 forms an inlet funnel 32, which connects co-30 axially to the proximal end of the cannula tube 10 and widens from the inner diameter of the cannula tube 10 in proximal direction to the diameter of the internal bore of the body part 18. Connected with this introduction funnel 32 in the axially proximal direction is the section of the body part 18 designed as luer-lock connection 34, which axially aligns with the cannula tube 10.

30

On the free end of the stranded connector 26, a plug-in connector junction or jack 36 is provided, with which the unipolar cannula can be plugged into an electrical nerve stimulator. The nerve stimulator sends out electrical voltage impulses of a few milliamps, which are conducted to the exposed distal end area 16 of the tip 14 through the stranded conductor 26, the wire 24, the connector junction 22, and the cannula tube 10, in order to emits an electrical nerve stimulation for localization of the distal tip 14.

On the outer circumference of the body part 18, grip flanges 38 are provided. An indicator notch 40 in one of the grip flanges 38 makes it possible to recognize the angled position of the facet cut 12.

In order to place the unipolar cannula, this is connected by means of the plug-in connector 36 to a nerve stimulator. The cannula tube 10 is stuck into the nerve sheath via the cut tip 14, whereby the respective position of the tip 14 can be controlled via the electro-stimulation. If the distal tip 14 of the cannula tube 10 is in place, then an injection hose can be connected to the Luer-lock connection 34 by means of a Luer-lock connector 42, in order to introduce an anesthetic via the

25

30

5

10

cannula tube 10. Alternatively, a needle can be connected to the Luer-lock connection 34 in order to control the position of the distal tip 14 by aspiration or in order to inject an anesthetic through this tip. If a catheter is to be placed for a long tern anesthesis, so this is - in certain cases after disconnection of the injection hose or the needle - axially introduced through the Luer-lock connection 34, whereby the inlet funnel 32 of the catheter tip leads into the cannula tube 10. The catheter tip passes axially out through the open distal end of the cannula tube 10 and is brought into the desired position. If the catheter is in place, so the unipolar cannula can be pulled out from the catheter from the back, whereby the catheter remains in its position.

Fig. 3 shows a further embodiment of the unipolar cannula. this corresponds with the previously described far as employed reference numbers are same embodiment, the reference is made to the above description.

In contrast to the embodiments of Figs. 1 and 2, the distal tip 14 of the unipolar cannula of Fig. 3 is designed as a Sprottetip, as this is described in DE 36 43 235 Cl. The distal tip 14 is designed as a closed-arched conical needle. Along the side behind the conical opening there is an outlet opening 44. The tip 14 is filled with a hardenable plastic 46, so that a ramp is formed on the inside of the cannula tube 10, which deflects the catheter tip out of the axial direction as it is slid distally towards the front in the cannula tube 10, so that the catheter exits from the side of the outlet opening 44 at an angle of approximately 30° to the axis of the cannula tube 10. The

cannula tube 10 is covered with insulation up to the conically-arched tip 14 so that also here only a distal end area 16 of the tip 14 with a maximal length of 1mm is exposed.
